## Data Management

### Track

## Data Stage Project (Intake 44/2024)

### Project Description

Retail industry scenario In this scenario, we use a “real world” retail industry scenario to demonstrate a typical star-schema data warehousing flow using IBM InfoSphere DataStage. Hopefully, you can then extrapolate/customize this process flow to address the unique starschema data warehousing requirements of your organization.

Our scenario assumes a fictitious national department store which decides to build a starschema based sales analysis data warehouse with the dimensions of customer, store, product, Over time, dimension attributes are expected to change, and the requirement is to preserve versions of these changes in the star-schema data warehouse in order to deliver accurate results with queries that relate to prior versions of dimension attributes. The data source for the starschema is an OLTP system

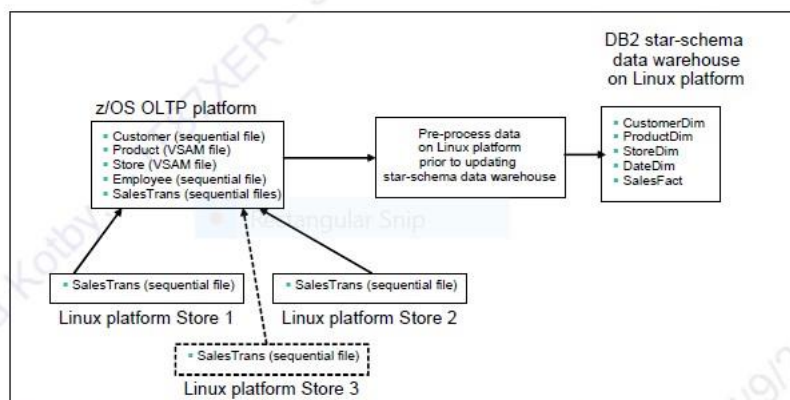

Figure 3-1 Retail industry scenario overview for WANTTHATSTUFF

- One time tasks (Day 0) involve the following actions:
- Designing the star-schema
  - Populating the dimension tables and fact table

c. Setting up for the recurring tasks.

Ex Star Schema:

- Store dimension table column MANAGER\_NAME

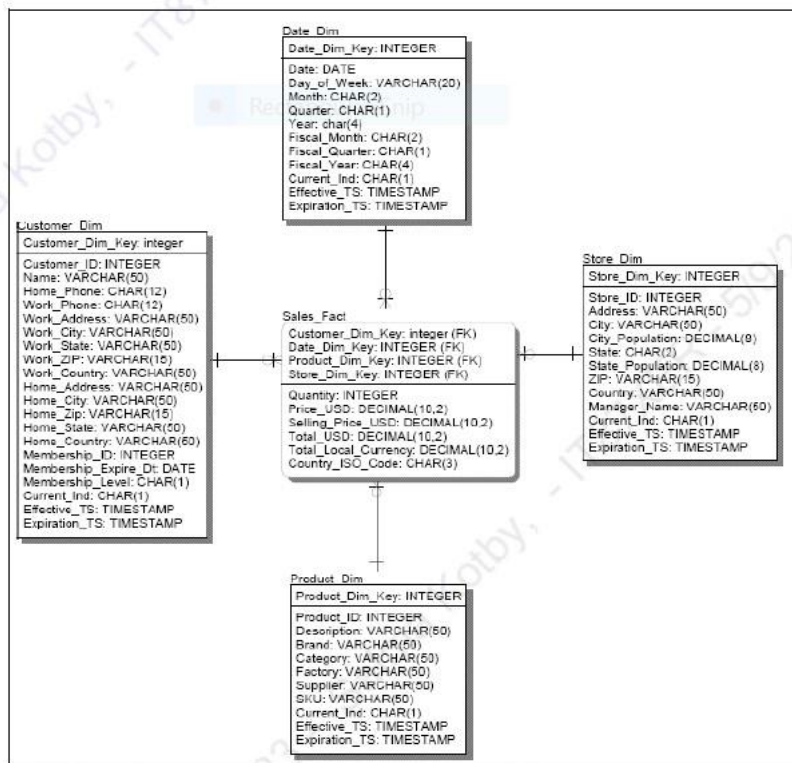

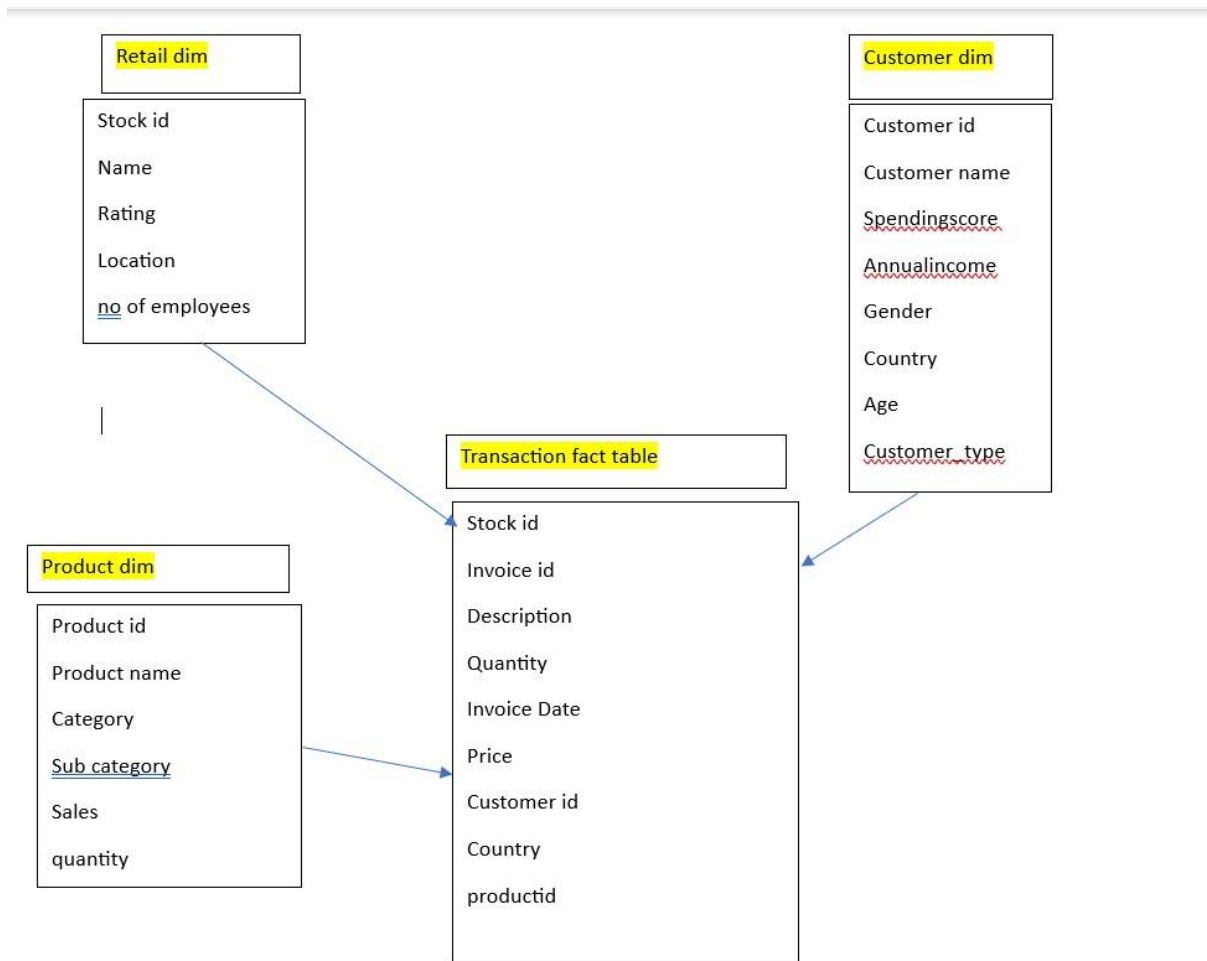

Figure 3-3 Star-schema of WantThatStuff's data warehouse

In our case study: we have three dimensions product, retail, customer , fact table "transactions"

As shown in next picture : I solve q1 and make model

In additional attached files , can you show samples of data

## Project Requirements

1. State the modeling process, translate the logical data model to a physical data model  
 "Done by me "I made this step and load samples into files in attached files
2. Using ETL tool , we need to create ETL solution to load this data into files or data bases based on business need ,you should read source data and make transformation on it to serve business need Questions:
  - 1) Need data mart that display each transaction for each customer based on type of customer "citizen" or "foreign" with information of it information of product and information of stock which buy with name file

“RETAIL\_DATA\_MART” with transformation upper case of all customer name column

2) based on question 1 read data mart “ACTIVATIONSALES\_DATA\_MART” Then answer the following business need:

- Display count of all transaction for each employee for each store
- Display max profit made by which customer type. Illustrate:  
customer type “foreign” make 5 transactions , customer type “citizen” makes 3 transactions.

So, max profit made by foreign customers.

Named DataMart “ACTIVATIONSALES\_DATA\_MART”

- Based on which customer make profit , give them Bouns  
Equation =  $\text{Annual\_Income} \$ * \text{SpendingScore} * 100$

Best of luck
